1. Willy WRT

In order to let all the hardware nodes communicate between eachother (and to Skylab) we used a OpenWRT router, named WillyWRT.

The router is installed on a Raspberry Pi and we used OpenWRT as the hardware is easily capable of running on a low powered device. We preferred to use another Raspberry Pi for this functionality, since next to its power requirements, it has a small formfactor and easily replacable aswell as the low purchase cost.

link::<https://downloads.openwrt.org/releases/>[Stable releases OpenWRT]

The current stable release of OpenWRT 18.06.1 is compatible with the Raspberry Pi however, the Wireless/bluetooth chip isn't supported. Therefore we used a Raspberry Pi 3B (with an older chipset).

1.1. Connection

We requested Windesheims ICT department to give WillyWRT Wireless access to the internet, so all phereplas can communicate to the outside world. The MAC-address is whitelisted and in the password documentation you can find the SSID and password.

1.2. Physical

The Wireless interface connects to the SSID provided by Windesheim, the LAN interface connects to a switch and provides (static) DHCP leases to the various hardware on physical Willy. We also applied a custom etc/hosts entry to make sure the ROS master can always resolve the FQDNs and/or hardware.

ROS communicates via the ROS master suggest to read up on this process as well. Make sure the different hardware nodes can communicate on DNS name and IP-address. This can take a lot of time troubleshooting.

1.3. VPN Tunnel

Another reason for us to choose for OpenWRT is to use an openVPN tunnel between Skylabs PFsense firewall and Willys LAN. Since configuring openVPN on openWRT can be challenging we have also exported the working configuration. [WillyWRT current configuration](#).
